**Question 1**

(a) We have

$$\nabla f(\mathbf{x}) = \begin{pmatrix} 2x_1 + 3x_2^3 - x_2 \\ 9x_1x_2^2 - x_1 \end{pmatrix}$$

so then we have

$$H_f(\mathbf{x}) = \begin{bmatrix} 2 & 9x_2^2 - 1 \\ 9x_2^2 - 1 & 18x_1x_2 \end{bmatrix}$$

as desired.

(b) Suppose  $\mathbf{x}^* = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$  be a stationary point of  $f$  on  $S$ . Since  $\nabla f(\mathbf{x}^*) = \begin{pmatrix} 2x_1 + 3x_2^3 - x_2 \\ 9x_1x_2^2 - x_1 \end{pmatrix}$ , it follows that

$$2x_1 + 3x_2^3 - x_2 = 0 \tag{1}$$

$$9x_1x_2^2 - x_1 = 0 \tag{2}$$

From (2) we have either  $x_1 = 0$  or  $x_2 = \frac{1}{3}$  (note that  $x_2 > 0$ ). If  $x_1 = 0$ , we see that  $3x_2^3 - x_2 = 0$ . Since  $x_2 > 0$ , we have  $x_2 = \sqrt{\frac{1}{3}}$ . If  $x_2 = \frac{1}{3}$ , then substitute to (1), we have  $x_1 = \frac{1}{9}$ . Thus, all stationary points of  $f$  in  $S$  are given by  $(0, \sqrt{\frac{1}{3}})$  and  $(\frac{1}{9}, \frac{1}{3})$

- (c)
- $\mathbf{x} = (0, \sqrt{\frac{1}{3}})$ . We have  $H_f(\mathbf{x}) = \begin{bmatrix} 2 & 2 \\ 2 & 0 \end{bmatrix}$ . Hence if  $a_1, a_2$  are two eigenvalues of  $H_f(\mathbf{x})$ , we have  $a_1a_2 = \det H_f(\mathbf{x}) = 2 \times 0 - 2 \times 2 = -4 < 0$ . Thus,  $a_1$  and  $a_2$  are on different sign, so we have  $H_f(\mathbf{x})$  is indefinite. Therefore, the point  $(0, \sqrt{\frac{1}{3}})$  is a saddle point.
  - $\mathbf{x} = (\frac{1}{9}, \frac{1}{3})$ . We have  $H_f(\mathbf{x}) = \begin{bmatrix} 2 & 0 \\ 0 & \frac{2}{3} \end{bmatrix}$  which is clearly positive definite since both eigenvalues 2 and  $\frac{2}{3}$  are positive. Therefore, the point  $(\frac{1}{9}, \frac{1}{3})$  is a local minimizer.

**Question 2**

Since  $B_r(\mathbf{0})$  is a nonempty (note that  $r > 0$ ) closed and bounded set and  $f$  is continuous over  $B_r(\mathbf{0})$ , Weierstrass theorem implies that there is a global minimizer  $\mathbf{x}^*$  of  $f$  over  $B_r(\mathbf{0})$ . Since  $\hat{x} \in B_r(\mathbf{0})$  it follows that  $f(\mathbf{x}^*) \leq f(\hat{x}) < \beta$ . Now, take any  $\mathbf{x} \in D$ . If  $\mathbf{x} \notin B_r(\mathbf{0})$ , we have  $f(\mathbf{x}) \geq \beta > f(\mathbf{x}^*)$ . If  $\mathbf{x} \in B_r(\mathbf{0})$ , then  $f(\mathbf{x}) \geq f(\mathbf{x}^*)$  since  $\mathbf{x}^*$  is a global minimizer of  $f$  over  $B_r(\mathbf{0})$ . We conclude  $\mathbf{x}^*$  is a global minimizer over  $f$  on entire  $D$ . QED.

**Question 3**

(a) We have

$$\begin{aligned}
 g(\mathbf{x}) &\geq \frac{\rho}{2} \left\| \mathbf{x} + \frac{\mathbf{b}}{\rho} \right\|^2 + f(\mathbf{0}) - \frac{1}{2\rho} \|\mathbf{b}\|^2 \\
 &\Leftrightarrow f(\mathbf{x}) + \frac{\rho}{2} \mathbf{x}^T \mathbf{x} \geq \frac{\rho}{2} \left( \mathbf{x} + \frac{\mathbf{b}}{\rho} \right)^T \left( \mathbf{x} + \frac{\mathbf{b}}{\rho} \right) + f(\mathbf{0}) - \frac{1}{2\rho} \mathbf{b}^T \mathbf{b} \\
 &\Leftrightarrow f(\mathbf{x}) + \frac{\rho}{2} \mathbf{x}^T \mathbf{x} \geq \frac{\rho}{2} \mathbf{x}^T \mathbf{x} + \frac{1}{2} \mathbf{x}^T \mathbf{b} + \frac{1}{2} \mathbf{b}^T \mathbf{x} + \frac{1}{2\rho} \mathbf{b}^T \mathbf{b} + f(\mathbf{0}) - \frac{1}{2\rho} \mathbf{b}^T \mathbf{b} \\
 &\Leftrightarrow f(\mathbf{x}) \geq \nabla f(\mathbf{0})^T \mathbf{x} + f(\mathbf{0})
 \end{aligned}$$

Hence, the inequality given in the problem is equivalent to the last inequality. However, the last inequality is true since  $f$  is convex, by tangent plane characterization.

Now since  $\lim_{\|\mathbf{x}\| \rightarrow \infty} \left\| \mathbf{x} + \frac{1}{\rho} \mathbf{b} \right\|^2 = \infty$ , it's easy to see that  $g$  is coercive. QED.

(b) Suppose  $\mathbf{u}$  and  $\mathbf{v}$  are two vectors. We consider any  $\alpha$  from interval  $(0, 1)$ . Then we have

$\alpha q(\mathbf{u}) + (1 - \alpha)q(\mathbf{v}) = \alpha h(A\mathbf{u} + \mathbf{b}) + (1 - \alpha)h(A\mathbf{v} + \mathbf{b}) \geq h(\alpha(A\mathbf{u} + \mathbf{b}) + (1 - \alpha)(A\mathbf{v} + \mathbf{b})) = h(A(\alpha\mathbf{u} + (1 - \alpha)\mathbf{v}) + \mathbf{b}) = q(\alpha\mathbf{u} + (1 - \alpha)\mathbf{v})$ . By definition,  $q$  is convex. Note that the inequality comes from the convexity of  $h$ . QED.

On the other hand, assume  $h$  is strictly convex. We shall show that  $q$  need not be strictly convex. Take an example if  $\text{nullity}(A) > 0$ . Clearly, such matrix  $A$  exists. Then  $A\mathbf{x} = 0$  has infinitely non-zero solutions. Take two different non-zero solutions  $\mathbf{u}$  and  $\mathbf{v}$ . Note that  $A\mathbf{u} = A\mathbf{v} = 0$ . Thus, we have  $A\left(\frac{\mathbf{u} + \mathbf{v}}{2}\right) = 0$ . Hence,  $\frac{q(\mathbf{u}) + q(\mathbf{v})}{2} = \frac{h(A\mathbf{u} + \mathbf{b}) + h(A\mathbf{v} + \mathbf{b})}{2} = h(\mathbf{b}) = h\left(A\left(\frac{\mathbf{u} + \mathbf{v}}{2}\right) + \mathbf{b}\right) = q\left(\frac{\mathbf{u} + \mathbf{v}}{2}\right)$ . Hence,  $q$  may not be strictly convex.

#### Question 4

(a) claim :  $\lambda_{\min}(\mathbf{Q})\|\mathbf{x}\|^2 \leq \mathbf{x}^T \mathbf{Q} \mathbf{x} \leq \lambda_{\max}(\mathbf{Q})\|\mathbf{x}\|^2$

Proof of claim : (no need to write the proof of this claim in the exam, just use it) Since  $\mathbf{Q}$  is symmetric, then there exists a  $n \times n$  orthogonal matrix  $\mathbf{P}$  such that  $\mathbf{D} = \mathbf{P}^T \mathbf{Q} \mathbf{P}$  for some diagonal matrix  $\mathbf{D}$ . (note that, it also mean  $\mathbf{Q} = \mathbf{P} \mathbf{D} \mathbf{P}^T$ )

Since  $\mathbf{P}$  is orthogonal, it follows that  $\mathbf{P}^T = \mathbf{P}^{-1}$ . Hence,  $\mathbf{P}$  is invertible and from there, we get the row vectors of  $\mathbf{P}$  are the basis of our  $\mathbb{R}^n$ . Therefore, if  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$  are row vectors of  $\mathbf{P}$ , we have the set  $\{c_1 \mathbf{v}_1 + c_2 \mathbf{v}_2 + \dots + c_n \mathbf{v}_n \mid c_1, c_2, \dots, c_n \in \mathbb{R}\}$  is actually equal to  $\mathbb{R}^n$ . Therefore, we conclude,

$$\{\mathbf{P} \mathbf{u} \mid \mathbf{u} \in \mathbb{R}^n\} = \mathbb{R}^n$$

Notice that if  $\lambda_1, \lambda_2, \dots, \lambda_n$  are all eigenvalues of  $\mathbf{Q}$ , it follows that

$$\mathbf{D} = \begin{pmatrix} \lambda_1 & 0 & \dots & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \lambda_n \end{pmatrix}$$

We pick an arbitrary vector in  $\mathbb{R}^n$ , i.e  $\mathbf{x}$ . Since  $\{\mathbf{P} \mathbf{u} \mid \mathbf{u} \in \mathbb{R}^n\} = \mathbb{R}^n$ , we get there is a vector  $\mathbf{y}$  such that  $\mathbf{P} \mathbf{y} = \mathbf{x}$ . Hence,  $\mathbf{x}^T \mathbf{Q} \mathbf{x} = (\mathbf{P} \mathbf{y})^T \mathbf{Q} \mathbf{P} \mathbf{y} = \mathbf{y}^T \mathbf{P}^T \mathbf{Q} \mathbf{P} \mathbf{y} = \mathbf{y}^T \mathbf{D} \mathbf{y}$ . Furthermore, if  $\mathbf{y} = (y_1 \ y_2 \ \dots \ y_n)^T$ , we have  $\mathbf{y}^T \mathbf{D} \mathbf{y} = \lambda_1 y_1^2 + \lambda_2 y_2^2 + \dots + \lambda_n y_n^2$ . Since  $\lambda_1, \lambda_2, \dots, \lambda_n$  are all positive and  $\lambda_{\min}(\mathbf{Q}) \leq \lambda_i \leq \lambda_{\max}(\mathbf{Q})$  for each  $i$ , it follows that

$\lambda_{\min}(\mathbf{Q}) (y_1^2 + y_2^2 + \dots + y_n^2) \leq \lambda_1 y_1^2 + \lambda_2 y_2^2 + \dots + \lambda_n y_n^2 \leq \lambda_{\max}(\mathbf{Q}) (y_1^2 + y_2^2 + \dots + y_n^2)$ , or equivalently, we get  $\lambda_{\min}(\mathbf{Q}) \mathbf{y}^T \mathbf{y} \leq \mathbf{y}^T \mathbf{D} \mathbf{y} \leq \lambda_{\max}(\mathbf{Q}) \mathbf{y}^T \mathbf{y}$ . We recall some facts first  $\mathbf{y} = \mathbf{P}^{-1} \mathbf{x}$  and  $\mathbf{P}^T = \mathbf{P}^{-1}$  which leads  $\mathbf{y} = \mathbf{P}^T \mathbf{x}$ . Another fact :  $\mathbf{P} \mathbf{P}^T = \mathbf{P} \mathbf{P}^{-1} = \mathbf{I}$ .

Finally,

$$\lambda_{\min}(\mathbf{Q}) \mathbf{y}^T \mathbf{y} \leq \mathbf{y}^T \mathbf{D} \mathbf{y} \leq \lambda_{\max}(\mathbf{Q}) \mathbf{y}^T \mathbf{y}$$

$$\begin{aligned}
&\Leftrightarrow \lambda_{\min}(\mathbf{Q})(\mathbf{P}^T \mathbf{x})^T \mathbf{P}^T \mathbf{x} \leq (\mathbf{P}^T \mathbf{x})^T \mathbf{D} \mathbf{P}^T \mathbf{x} \leq \lambda_{\max}(\mathbf{Q})(\mathbf{P}^T \mathbf{x})^T \mathbf{P}^T \mathbf{x} \\
&\Leftrightarrow \lambda_{\min}(\mathbf{Q}) \mathbf{x}^T (\mathbf{P}^T)^T \mathbf{P}^T \mathbf{x} \leq \mathbf{x}^T (\mathbf{P}^T)^T \mathbf{D} \mathbf{P}^T \mathbf{x} \leq \lambda_{\max}(\mathbf{Q}) \mathbf{x}^T (\mathbf{P}^T)^T \mathbf{P}^T \mathbf{x} \\
&\Leftrightarrow \lambda_{\min}(\mathbf{Q}) \mathbf{x}^T \mathbf{P} \mathbf{P}^T \mathbf{x} \leq \mathbf{x}^T \mathbf{P} \mathbf{D} \mathbf{P}^T \mathbf{x} \leq \lambda_{\max}(\mathbf{Q}) \mathbf{x}^T \mathbf{P} \mathbf{P}^T \mathbf{x} \\
&\Leftrightarrow \lambda_{\min}(\mathbf{Q}) \mathbf{x}^T \mathbf{x} \leq \mathbf{x}^T \mathbf{Q} \mathbf{x} \leq \lambda_{\max}(\mathbf{Q}) \mathbf{x}^T \mathbf{x}
\end{aligned}$$

Claim is proved.

From our claim, we get  $\frac{1}{\lambda_{\max}(\mathbf{Q})\|\mathbf{x}\|^2} \leq \frac{1}{\mathbf{x}^T \mathbf{Q} \mathbf{x}} \leq \frac{1}{\lambda_{\min}(\mathbf{Q})\|\mathbf{x}\|^2}$ . Furthermore, we also get  $\forall \mathbf{x} \in L_\alpha$ ,  $\frac{1}{\lambda_{\max}(\mathbf{Q})\|\mathbf{x}\|^2} \leq \frac{1}{\alpha} \leq \frac{1}{\lambda_{\min}(\mathbf{Q})\|\mathbf{x}\|^2}$ . Multiplying the inequality by a positive number  $\alpha\|\mathbf{x}\|^2$ , we get  $\frac{\alpha}{\lambda_{\max}(\mathbf{Q})} \leq \|\mathbf{x}\|^2 \leq \frac{\alpha}{\lambda_{\min}(\mathbf{Q})}$  as desired. QED.

- (b) We have  $\kappa(\mathbf{Q}) = \left(\frac{\lambda_{\max}(\mathbf{Q})}{\lambda_{\min}(\mathbf{Q})}\right)^2 = \left(\frac{2.8\text{cm}}{0.7\text{cm}}\right)^2 = 16$ . (the value 2.8 cm is the major axis, and 0.7 cm is minor axis, one can also prove that  $\frac{\lambda_{\max}}{\lambda_{\min}} = \frac{\text{major axis}}{\text{minor axis}}$ ). Hence, the rate of convergence is given by  $\rho(\mathbf{Q}) = \left(\frac{16-1}{16+1}\right)^2 = \frac{225}{289}$ . Since  $\epsilon = 10^{-8}$ , we get the number of iterations needed is given by  $k = \left\lceil \frac{\log \epsilon}{\log \rho(\mathbf{Q})} \right\rceil + 1 = 75$

- (c) The solution  $t^*$  is the solution of the following problem :

$$\min g(t) = f(\mathbf{x} + t\mathbf{p}) \text{ with } t \geq 0$$

It happens that  $g'(t^*) = 0$ . Note also  $g'(t) = \langle \nabla f(\mathbf{y} + t\mathbf{p}), \mathbf{p} \rangle$ . Furthermore, since  $f$  is quadratic, it's well known that  $\nabla f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{c}$ . It follows that :

$$\begin{aligned}
0 = g'(t^*) &= \langle \nabla f(\mathbf{y} + t^*\mathbf{p}), \mathbf{p} \rangle \\
&= \langle \mathbf{Q}(\mathbf{y} + t^*\mathbf{p}) + \mathbf{c}, \mathbf{p} \rangle \\
&= \langle \mathbf{Q}\mathbf{y} + \mathbf{c} + t^*\mathbf{Q}\mathbf{p}, \mathbf{p} \rangle \\
&= \langle \mathbf{Q}\mathbf{y} + \mathbf{c}, \mathbf{p} \rangle + t^* \langle \mathbf{Q}\mathbf{p}, \mathbf{p} \rangle \\
&= \langle \nabla f(\mathbf{y}), \mathbf{p} \rangle + t^* \langle \mathbf{Q}\mathbf{p}, \mathbf{p} \rangle
\end{aligned}$$

From here, we get  $t^* = -\frac{\langle \nabla f(\mathbf{y}), \mathbf{p} \rangle}{\langle \mathbf{Q}\mathbf{p}, \mathbf{p} \rangle} = -\frac{\nabla f(\mathbf{y})^T \mathbf{p}}{\mathbf{p}^T \mathbf{Q} \mathbf{p}}$ .

### Question 5

Before we begin, let us change the problem a little bit into our regular NLP. The problem is :

$$\begin{aligned}
\min \quad & f(\mathbf{x}) := x_1 + x_2 \\
\text{s.t} \quad & h_1(\mathbf{x}) := -(x_1 + 1)^2 - x_2^2 \leq -1 \\
& h_2(\mathbf{x}) := x_1^2 + 2x_2^2 \leq 3
\end{aligned}$$

We shall solve this equivalent NLP problem for our remaining problem instead of the original one. Some facts :

$$\begin{aligned}
\text{(i)} \quad & \nabla f(\mathbf{x}) = \begin{pmatrix} 1 \\ 1 \end{pmatrix} \\
\text{(ii)} \quad & \nabla h_1(\mathbf{x}) = \begin{pmatrix} -2x_1 - 2 \\ -2x_2 \end{pmatrix}
\end{aligned}$$

$$(iii) \nabla h_2(\mathbf{x}) = \begin{pmatrix} 2x_1 \\ 4x_2 \end{pmatrix}$$

$$(iv) H_f(\mathbf{x}) = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$$

$$(v) H_L(\mathbf{x}) = \mu_1 \begin{pmatrix} -2 & 0 \\ 0 & 2 \end{pmatrix} + \mu_2 \begin{pmatrix} 2 & 0 \\ 0 & 4 \end{pmatrix}$$

(a) Let  $\mathbf{x} = (x_1 \ x_2)^T$  be an arbitrary feasible point.

**Case 1** None of  $h_1, h_2$  are active at  $\mathbf{x}$ . Clearly,  $\mathbf{x}$  is regular in this case.

**Case 2**  $h_1$  is active, but  $h_2$  is not. Then we have  $(x_1 + 1)^2 + x_2^2 = 1$ . Hence,  $\mathbf{x} \neq \begin{pmatrix} -1 \\ 0 \end{pmatrix}$  as otherwise, the previous equality would not be satisfied. However, looking back at (ii), we know that  $\nabla h_1(\mathbf{x}) = 0$  iff  $\mathbf{x} = \begin{pmatrix} -1 \\ 0 \end{pmatrix}$ , so then we have  $\nabla h_1(\mathbf{x}) \neq 0$ . Hence, the set  $J(\mathbf{x}) = \{\nabla h_1(\mathbf{x})\}$  is linearly independent. Therefore,  $x$  is regular.

**Case 3**  $h_2$  is active, but  $h_1$  is not. Then we have  $x_1^2 + 2x_2^2 = 3$ . Hence,  $\mathbf{x} \neq \begin{pmatrix} 0 \\ 0 \end{pmatrix}$  as otherwise, the previous equality would not be satisfied. However, looking back at (iii), we know that  $\nabla h_2(\mathbf{x}) = 0$  iff  $\mathbf{x} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$ , so then we have  $\nabla h_2(\mathbf{x}) \neq 0$ . Hence, the set  $J(\mathbf{x}) = \{\nabla h_2(\mathbf{x})\}$  is linearly independent. Therefore,  $x$  is regular.

**Case 4** Both  $h_1$  and  $h_2$  are active. Hence we have

$$(x_1 + 1)^2 + x_2^2 = 1 \tag{1}$$

$$x_1^2 + 2x_2^2 = 3 \tag{2}$$

Now, multiply (1) by 2 and subtract it by (2), we get  $2(x_1 + 1)^2 - x_1^2 = -1$  which is equivalent with  $x_1^2 + 4x_1 + 3 = 0 \Leftrightarrow x_1 = -1$  or  $x_1 = -3$ . If  $x_1 = -1$ , substitute back to (2), we get  $x_2^2 = 1$ , so  $x_2 = \pm 1$ . If  $x_1 = -3$ , substitute back to (2) we get  $x_2^2 = -3$ , a contradiction. Hence, if  $h_1, h_2$  is active, then  $x_1 = 1$  and  $x_2 = \pm 1$ .....(3)

For  $x_1 = 1$  and  $x_2 = 1$ , we get  $\nabla h_1(\mathbf{x}) = \begin{pmatrix} -4 \\ -2 \end{pmatrix}$  and  $\nabla h_2(\mathbf{x}) = \begin{pmatrix} 2 \\ 4 \end{pmatrix}$

For  $x_1 = 1$  and  $x_2 = -1$ , we get  $\nabla h_1(\mathbf{x}) = \begin{pmatrix} -4 \\ 2 \end{pmatrix}$  and  $\nabla h_2(\mathbf{x}) = \begin{pmatrix} 2 \\ -4 \end{pmatrix}$

In both cases, two vectors  $\nabla h_1(\mathbf{x})$  and  $\nabla h_2(\mathbf{x})$  are not multiply of each other. Hence, the set  $J(\mathbf{x}) = \{\nabla h_1(\mathbf{x}), \nabla h_2(\mathbf{x})\}$  is linearly independent. We conclude  $x$  is regular.

From all cases, we see that  $x$  is regular. Hence, all feasible points are regular. QED.

(b) KKT Conditions :

$$\begin{pmatrix} 1 \\ 1 \end{pmatrix} + \mu_1 \begin{pmatrix} -2x_1 - 2 \\ -2x_2 \end{pmatrix} + \mu_2 \begin{pmatrix} 2x_1 \\ 4x_2 \end{pmatrix} = 0$$

$$\mu_1, \mu_2 \geq 0$$

$$\mu_i h_i(\mathbf{x}) = 0 \text{ for } i = 1, 2$$

(c) We solve our KKT condition.

**Case 1** None of  $h_1, h_2$  are active at  $\mathbf{x}$ .

Then we have  $\mu_1 = \mu_2 = 0$ , so our KKT conditions become  $\begin{pmatrix} 1 \\ 1 \end{pmatrix} = 0$ , a contradiction.

**Case 2** Only  $h_1$  that is active at  $\mathbf{x}$ .

Then we have  $\mu_2 = 0$ , so our KKT conditions become  $\mu_1 \begin{pmatrix} 2x_1 + 2 \\ 2x_2 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ . Together with the fact that  $h_1$  is active, we have altogether three equations :

$$2x_1 + 2 = \frac{1}{\mu_1} \quad (1)$$

$$2x_2 = \frac{1}{\mu_1} \quad (2)$$

$$(x_1 + 1)^2 + x_2^2 = 1 \quad (3)$$

From third equation, we have  $(2x_1 + 2)^2 + (2x_2)^2 = 4$ , so we have  $2 \left( \frac{1}{\mu_1} \right)^2 = 4$ . Since  $\mu_1 \geq 0$ , we see that  $\mu_1 = \frac{1}{\sqrt{2}}$ . Hence,  $x_1 = \frac{\sqrt{2}-2}{2}$  and  $x_2 = \frac{\sqrt{2}}{2}$ . Since  $x_1^2 + 2x_2^2 = \frac{3}{2} - \sqrt{2} + 1 < 3$  it follows that  $\mathbf{x} = \begin{pmatrix} \frac{\sqrt{2}-2}{2} \\ \frac{\sqrt{2}}{2} \end{pmatrix}$  is indeed a feasible point. Hence,  $\mathbf{x}$  is a KKT point.

**Case 3** Only  $h_2$  is active at  $\mathbf{x}$ .

Then we have  $\mu_1 = 0$ , so our KKT conditions become  $\mu_2 \begin{pmatrix} 2x_1 \\ 4x_2 \end{pmatrix} = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$ . Together with the fact that  $h_2$  is active, we have altogether three equations :

$$2x_1 = \frac{-1}{\mu_2} \quad (1)$$

$$4x_2 = \frac{-1}{\mu_2} \quad (2)$$

$$x_1^2 + 2x_2^2 = 3 \quad (3)$$

Then we have  $x_1 = \frac{-1}{2\mu_2}$  and  $x_2 = \frac{-1}{4\mu_2}$  so substitute to third equation, we have  $\left( \frac{1}{4} + \frac{1}{8} \right) \frac{1}{\mu_2^2} = 3$ . Since  $\mu_2 \geq 0$  then we have  $\mu_2 = \frac{1}{\sqrt{8}}$ . From there, we get  $x_1 = -\sqrt{2}$  and  $x_2 = -\frac{\sqrt{2}}{2}$ . Since  $(x_1 + 1)^2 + x_2^2 = \frac{7}{2} - 2\sqrt{2} < 1$  it follows that the point that we get is not a feasible point.

**Case 4**  $h_1, h_2$  are active at  $\mathbf{x}$ .

From the statement (3) at part a, at case 4, we see that if  $h_1, h_2$  are active, then  $x_1 = 1$  and  $x_2 = \pm 1$ . Furthermore, from our KKT conditions we have

$$\mu_1(2x_1 + 2) - \mu_2(2x_1) = 1 \quad (1)$$

$$\mu_1(2x_2) - \mu_2(4x_2) = 1 \quad (2)$$

If  $x_1 = 1$  and  $x_2 = 1$  we have  $4\mu_1 - 2\mu_2 = 1$  and  $2\mu_1 - 4\mu_2 = 1$ . Solving two equations, we get  $\mu_1 = \mu_2 = -\frac{1}{2}$  which is a contradiction since  $\mu_1, \mu_2 \geq 0$ .

If  $x_1 = 1$  and  $x_2 = -1$  we have  $4\mu_1 - 2\mu_2 = 1$  and  $-2\mu_1 + 4\mu_2 = 1$  which in turn give us  $\mu_1 = \mu_2 = \frac{1}{2}$ .

Altogether, there are two KKT points, namely  $(\mathbf{x}; \mu) = \left( \begin{pmatrix} 1 \\ -1 \end{pmatrix}; \begin{pmatrix} \frac{1}{2} \\ \frac{1}{2} \end{pmatrix} \right), \left( \begin{pmatrix} \frac{\sqrt{2}-2}{2} \\ \frac{\sqrt{2}}{2} \end{pmatrix}; \begin{pmatrix} \frac{1}{\sqrt{2}} \\ 0 \end{pmatrix} \right)$

(d) •  $(\mathbf{x}; \mu) = \left( \begin{pmatrix} 1 \\ -1 \end{pmatrix}; \begin{pmatrix} \frac{1}{2} \\ \frac{1}{2} \end{pmatrix} \right)$

We have  $H_L(\mathbf{x}) = \mu_1 \begin{pmatrix} -2 & 0 \\ 0 & 2 \end{pmatrix} + \mu_2 \begin{pmatrix} 2 & 0 \\ 0 & 4 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 3 \end{pmatrix}$ . Now,  $H_L(\mathbf{x})$  is a positive semidefinite

matrix. Hence, the second order condition is satisfied; i.e  $\mathbf{y}^T H_L(\mathbf{x}) \mathbf{y} \geq 0$  for all  $\mathbf{y} \in T(\mathbf{x})$  where  $T(\mathbf{x})$  is the tangent space to the feasible set at  $\mathbf{x}$

$$\bullet (\mathbf{x}; \mu) = \left( \begin{pmatrix} \frac{\sqrt{2}-2}{2} \\ \frac{\sqrt{2}}{2} \end{pmatrix}; \begin{pmatrix} \frac{1}{\sqrt{2}} \\ 0 \end{pmatrix} \right)$$

We have  $H_L(\mathbf{x}) = \begin{pmatrix} -\sqrt{2} & 0 \\ 0 & \sqrt{2} \end{pmatrix}$  which is negative semidefinite. In other words,  $\mathbf{y}^T H_L(\mathbf{x}) \mathbf{y} \geq 0$  for all  $\mathbf{y} \in T(\mathbf{x})$  where  $T(\mathbf{x})$  is the tangent space to the feasible set at  $\mathbf{x}$  if and only if  $\mathbf{y}^T H_L(\mathbf{x}) \mathbf{y} = 0$  for all  $\mathbf{y} \in T(\mathbf{x})$ . Now, since  $h_2$  is inactive at  $\mathbf{x}$ , we have  $T(\mathbf{x}) = \{\mathbf{y} \mid \nabla h_1(\mathbf{x})^T \mathbf{y} = 0\}$ . Since  $\nabla h_1(\mathbf{x}) = \begin{pmatrix} -\sqrt{2} \\ -\sqrt{2} \end{pmatrix}$ , it follows that  $\left\{ \begin{pmatrix} u \\ -u \end{pmatrix} \mid u \in \mathbb{R} \right\} = T(\mathbf{x})$ . Take any vector from  $T(\mathbf{x})$ , say  $\begin{pmatrix} y \\ -y \end{pmatrix}$ . Then, we have  $(y \ -y) \begin{pmatrix} -\sqrt{2} & 0 \\ 0 & \sqrt{2} \end{pmatrix} \begin{pmatrix} y \\ -y \end{pmatrix} = 0$ . Hence,  $H_L(\mathbf{x})$  is positive semidefinite on  $T(\mathbf{x})$  and the second order KKT condition is satisfied.

### Question 6

- (a) The Lagrangian function is  $L(\mathbf{x}, \mu) = -3x_1 - 2x_2 + \mu(x_1^2 + x_1x_2 + x_2^2 - 4)$  for  $\mu \geq 0$ . We shall minimize the function  $L$  on  $x = (x_1; x_2)$  over the set  $X$ . Now if  $\mu = 0$ , it follows that  $L(\mu) = -3x_1 - 2x_2$ . Since taking  $x_2 = 0$  and taking  $x_1 \rightarrow \infty$ , leads us to  $L(\mathbf{x}, \mu) = -\infty$ , it follows that  $\inf\{L(\mathbf{x}, \mu)\} = -\infty$ . If  $\mu > 0$ , it follows that  $L(\mathbf{x}, \mu) = \mathbf{x}^T \begin{pmatrix} \mu & \frac{\mu}{2} \\ \frac{\mu}{2} & \mu \end{pmatrix} \mathbf{x} - (3 \ 2) \mathbf{x} - 4\mu$ . Hence,  $L(\mathbf{x}, \mu)$  is a quadratic function. Furthermore, the matrix  $\begin{pmatrix} 2\mu & \mu \\ \mu & 2\mu \end{pmatrix}$  has  $\Delta_1 = 2\mu$  and  $\Delta_2 = 3\mu^2$  which both are positive. Hence,  $L(\mathbf{x}, \mu)$  has a global minimizer over  $\mathbb{R}^2$  and it occurs when  $\begin{pmatrix} 2\mu & \mu \\ \mu & 2\mu \end{pmatrix} \mathbf{x} = \begin{pmatrix} 3 \\ 2 \end{pmatrix}$ . We have a solution  $\mathbf{x} = \begin{pmatrix} \frac{4}{3\mu} \\ \frac{1}{3\mu} \end{pmatrix}$  which is inside  $X$ . Hence, the global minimizer of  $L$  over  $\mathbb{R}^2$  is also inside  $X$ . Therefore, the infimum is achieved when  $\mathbf{x}$  is a global minimizer of  $L$  over  $\mathbb{R}^2$ . Now we have  $L(\mathbf{x}, \mu) = \mathbf{x}^T \begin{pmatrix} \mu & \frac{\mu}{2} \\ \frac{\mu}{2} & \mu \end{pmatrix} \mathbf{x} - (3 \ 2) \mathbf{x} - 4\mu = \frac{1}{2} \mathbf{x}^T \begin{pmatrix} 3 \\ 2 \end{pmatrix} - (3 \ 2) \mathbf{x} - 4\mu = -\left(\frac{3}{2} \ 1\right) \mathbf{x} - 4\mu = -\frac{7}{3\mu} - 4\mu$ . Hence, the Lagrangian Dual Problem is given by :

$$\begin{aligned} \max \quad & \theta(\mu) = -\frac{7}{3\mu} - 4\mu \\ \text{s.t} \quad & \mu > 0 \end{aligned}$$

- (b) This has a lot of ways to do that. We can use Calculus, that is the first derivative must be zero. One can also make a no-square is negative equation. The findings presented here uses the AM-GM inequality.

By the AM-GM inequality, we get  $-\theta(\mu) = \frac{7}{3\mu} + 4\mu \geq 2\sqrt{\frac{28}{3}}$  with equality happens when  $(\mu^*)^2 = \frac{7}{12}$  which leads to  $\mu^* = \sqrt{\frac{7}{12}}$ . Hence,  $\theta(\mu) = -\frac{7}{3\mu} - 4\mu$  is maximized when  $\mu^* = \sqrt{\frac{7}{12}}$ .

- (c) Let  $\mathbf{x}^* = \begin{pmatrix} \frac{4}{3\mu^*} \\ \frac{1}{3\mu^*} \end{pmatrix}$ . Since  $f(\mathbf{x}^*) = -\frac{14}{3\mu^*} = -2\sqrt{\frac{28}{3}}$ , it follows that  $f(\mathbf{x}^*) = \theta(\mu^*)$ . Hence, the  $\mathbf{x}^*$  is a global solution to the NLP.

### Question 7

- (a) Since  $\mathbf{x}^*$  is a KKT point, we have  $\mu^*h(\mathbf{x}^*) = 0$ . Furthermore, we also have  $g(\mathbf{x}^*) = 0$ . Hence  $L(\mathbf{x}^*, \lambda^*, \mu^*) = f(\mathbf{x}^*) + \lambda^*g(\mathbf{x}^*) + \mu^*h(\mathbf{x}^*) = f(\mathbf{x}^*)$ . QED.
- (b) Since  $\mathbf{x}^*$  is feasible, we have  $\mu h(\mathbf{x}^*) \leq 0$  and  $g(\mathbf{x}^*) = 0$ . Hence, we have  $L(\mathbf{x}^*, \lambda, \mu) = f(\mathbf{x}^*) + \lambda g(\mathbf{x}^*) + \mu h(\mathbf{x}^*) \leq f(\mathbf{x}^*) = L(\mathbf{x}^*, \lambda^*, \mu^*)$ . The last equality comes from part a. QED.
- (c) Claim :  $L(\mathbf{x}^*, \lambda^*, \mu^*) \leq L(\mathbf{x}, \lambda^*, \mu^*)$ .

Proof of claim : since  $f, h$  is convex and  $g$  is affine, we have :

$$\begin{aligned} f(\mathbf{x}) &\geq f(\mathbf{x}^*) + (\mathbf{x} - \mathbf{x}^*)\nabla f(\mathbf{x}^*) \\ \lambda^*g(\mathbf{x}) &= \lambda^*g(\mathbf{x}^*) + (\mathbf{x} - \mathbf{x}^*)\lambda^*\nabla g(\mathbf{x}^*) \\ \mu^*h(\mathbf{x}) &\geq \mu^*h(\mathbf{x}^*) + (\mathbf{x} - \mathbf{x}^*)\mu^*\nabla h(\mathbf{x}^*) \end{aligned}$$

Taking the sum of three equations, we get  $L(\mathbf{x}, \lambda^*, \mu^*) \geq L(\mathbf{x}^*, \lambda^*, \mu^*) + (\mathbf{x} - \mathbf{x}^*)(\nabla f(\mathbf{x}^*) + \lambda^*\nabla g(\mathbf{x}^*) + \mu^*\nabla h(\mathbf{x}^*)) = L(\mathbf{x}^*, \lambda^*, \mu^*)$

Combining that with inequality at part b, we get the result. QED.
